Abstract. In this paper we present a synthesis method of calcium phosphate bioceramics such as hydroxyapatite, the mineral component of bones and hard tissue in mammals. Investigations carried out have confirmed obtaining of hydroxyapatite characterized by a high degree of crystallinity, purity, and a good stoichiometry.

Keywords. Hydroxyapatite, chemical co-precipitation, x – ray diffraction, X-ray fluorescence spectroscopy

1. INTRODUCTION

In this paper we present a synthesis method of calcium phosphate bioceramics such as hydroxyapatite, the mineral component of bones and hard tissue in mammals. Hydroxyapatite ceramics are of considerable interest for clinical applications due to their high biocompatibility with hard tissues, particularly, bone and teeth tissue [1, 2]. Hydroxyapatite is the most stable calcium phosphate in an aqueous solution, they solubility depend on numerous factors such as: Ca/P ratio, crystallinity index, porosity, particle size and foreign ions such as carbonates, fluorine, chloride or magnesium ions, which are often present in hydroxyapatite as impurities [3]. The production of synthetic ceramic hydroxyapatite powders may be classified under two main headings: processing of hard tissue from mammal or coral, and laboratory synthesis (chemical co precipitation, reactions in solid state, hydrothermal methods, sol – gel process) [4, 5, 6]. The proposed method is based on chemical co precipitation process. The hydroxyapatite powders are obtained after the chemical reaction of inorganic oxide solution. As the starting reagent, analytical grade Ca(OH)₂, H₃PO₄ and NH₃OH were used. Properties of the chemicals used to produce hydroxyapatite powders are summarized in Table 1.

</tbody>
</table>

The chemical equation that describes the reaction is:

\[ 10\text{Ca(OH)}_2 + 6\text{H}_3\text{PO}_4 \rightarrow \text{Ca}_10(\text{PO}_4)_6(\text{OH})_2 + 18\text{H}_2\text{O} \]

A stoichiometric hydroxyapatite was prepared using the precipitation reaction between 0.3 moles calcium hydroxide, Ca(OH)₂ in 500 ml distilled water and 0.18 moles orthophosphoric acid, H₃PO₄ in 200 ml distilled water, as we present in figure 1.

In order to obtain a hydroxyapatite slurry, H₃PO₄ solution was added by dropwise, for the 1 - 4 hours over the alkaline solution based on Ca(OH)₂, in condition of intense stirring.

Fig. 2. Flow chart for synthesis of hydroxyapatite by chemical co-precipitation process

In order to obtain a stoichiometric hydroxyapatite, therefore Ca / P = 1.67, the pH of the solution was continuously adjusted, pH > 7, by the addition of NH₄OH [3].

The reaction mixture was stirred for several hours at a temperature between 20 and 80°C and then aged for up to 48 hours. In order to remove any impurities, the precipitate was filtered and washed with distilled water and / or ethanol. Precipitites were filtered by using a Buehler funnel and washed several times with distilled water. The filtered precipitate was oven dried at 80°C and then ground to a powder in an mortar and pestle. In the next step, hydroxyapatite powders was calcined at 800°C for 30 min. Finally, powders was then ball milled, using a porcelain mill pot with tungsten carbide balls, for 1 hour.

2.2 Characterization technique

Investigations of hydroxyapatite powder samples were made using a Seifert X - ray diffractometer with CuKα = 1.5405 Å radiation generated at a voltage of 40 kV and a current of 30 mA. The samples were examined from 20° to 60° with a step size of 0.05 ° 20/s. X - ray analysis was used to assess the present phases, the degree of crystallinity and size of crystallites, in case of hydroxyapatite studied. Identification of phases was achieved by comparing the diffraction patterns of hydroxyapatite with ICDD – PDF2 standards.

</tbody>
</table>

Also, the calcium and phosphorus contents of hydroxyapatite powders were determined by X-ray fluorescence (XRF) using a Panalytical Axios spectrometer. In order to produce high-quality samples, for a highly accurate and reproducible analysis an automated sample preparation system Pearl X’3 was used.

3. RESULTS

Figure 2 show the X - ray diffraction patterns for hydroxyapatite samples, according with experimental procedure above described, and the diffraction lines for file PDF 9 – 432.

All xrd patterns shows peaks characteristic of hydroxyapatite, both present in standards and in literature. The major phase, as expected, is hydroxyapatite, which is confirmed by comparing data obtained with the standard ICDD - PDF2 (The International Centre for Diffraction Data - Powder Diffraction File 2) and applications Match 1.9 - Crystal Impact Inc. and PowderX Ver 2004-04.72 Pro. In figure 2a are present xrd pattern for as dried hydroxyapatite sample. This pattern revealed the presence of an important amorphous phase.

The proportion of amorphous phase decreases with increasing of heat treatment temperature at 800°C, respectively 1200°C, as are presented in figure 2b and figure 2c. In case of samples heat treated at temperatures above 800°C, hydroxyapatite peaks located at 25.88; 31.77; 32.19; 32.90; 34.04; 39.82; 46.71; 49.46; 53.14 (20) are clearly evidenced. The shape of these peaks become more sharper once the temperature of heat treatment increase at 1200°C.
The Scientific Bulletin of VALAHIA University – MATERIALS and MECHANICS – Nr. 5 (year 8) 2010

Figure 2. X-ray diffraction patterns of hydroxyapatite samples:
a) sample as precipitated b) sample after heat treatment at 800°C; c) sample after heat treatment at 1200°C; d) standard sample

This shape is attributed to increased size of hydroxyapatite crystallites. To estimate the size of crystallites is using Debye-Scherer relationship:

\[ \tau = \frac{K \lambda}{2 \cos(\theta) \cdot \text{FWHM}} \]

where: \( \tau \) is defined as the full width of the intensity distribution at half of the maximum intensity (FWHM – full width at half maximum) and give the difference between the two 2 theta values, in radians; FWHM = \( 2 \theta_{\text{max}} - 2 \theta_{\text{min}} \) [20].

Figure 3. Generic example of full width at half maximum representation

K = constant dependent on crystallite shape, 0.8 < K < 1.1; \( \lambda \) is the wavelength of monochromatic radiation, \( \lambda_{\text{CuK} \alpha} = 1.5405 \text{Å} \), and \( \theta \) is the Bragg angle, in degree.

As shown in table 3, based on Debye-Scherer relationship is in the range 10-58 nm. These data are consistent with those presented for the standard sample analysis and the literature. The estimated crystallites size of hydroxyapatite are in according with data obtained regarding the crystallinity degree. In terms of x-ray diffraction, the crystallinity parts give sharp narrow diffraction peaks and the amorphous component gives a very broad peak (halo). The ratio between these intensities can be used to calculate the amount of crystallinity in the material.

An estimation regarding crystallinity degree and relative crystallinity, in case of hydroxyapatite samples, are presented in table 4. The relative crystallinity was calculated as a ratio between both crystallinity degrees of hydroxyapatite samples obtained in laboratory and standard sample.

The XRD analysis results show that secondary phases such as : \( \beta - \text{tricalcium phosphate}, \beta - \text{Ca}_3(\text{PO}_4)_2 \), and calcium oxide (CaO) were not found. The only relevant peak corresponding to secondary phases, in this case : \( \alpha - \text{tricalcium phosphate}, \alpha - \text{Ca}_3(\text{PO}_4)_2 \), was identified at 30.73 (20) Relative intensity of the peak situated at 30.73 (20) will decrease proportionally with heat treatment temperature applied to the hydroxyapatite powders studied.
Results of x-ray diffraction analysis are supported by the semi quantitative chemical analysis achieved by X-ray fluorescence (XRF). In table 5 are presented the results of XRF analysis for the sample as dried, heat treated at 1200°C and, for a commercial hydroxyapatite.

The chemical analysis by X-ray fluorescence reveals a good stoichiometry, very close to the theoretical value, Ca / P = 1.67, for the sample heat treated at 1200°C. Thus, an important role in achieving these results had purity of reactants and the most important parameters involved in the synthesis process: pH level of reaction, reactants addition rate, stirring speed of reactants, reaction temperature. They play an important role in obtaining the proper products for their intended applications.

4. CONCLUSION

The proposed method for the synthesis of hydroxiapatite powders led to obtaining a product with a high degree of crystallinity and purity. The crystallinity degree and the relative crystallinity was 82.5%, respectively 93.53%, in case of the sample heat treated at 1200°C.

The results above mentioned was compared with data obtained from hydroxyapatite X - ray diffraction patterns published in American Mineralogist Structure Database (AMCSD). The positive trend regarding crystallinity degree once with increasing of heat treatment temperature is confirmed by the estimated values of hydroxyapatite crystallites. The X – ray diffraction analysis did not reveal the presence of calcium phosphate compounds such as: \( \beta - Ca_3(PO_4)_2 \), \( \alpha - Ca_3(PO_4)_2 \), CaO as secondary phases. The results of semi quantitative chemical analysis achieved by X-ray fluorescence (XRF) confirm that a hydroxyapatite samples obtained in laboratory has a calcium phosphorous ratio between 1.66 and 1.74, very close to the stoichiometric value.

An essential role in obtaining this value was the heat treatment applied and the optimal choice of parameters involved in the synthesis process, such as: pH level of reaction, reactants addition rate, stirring speed of reactants and reaction temperature.
