Abstract. This paper analyze through the finite elements method (FEM) a turbine shaft – main shaft subassembly from a average power hydrodynamic clutch included in a driveline agricultural machinery. The static and dynamic analysis of turbine shaft – main shaft subassembly was made. A three-dimensional model of the turbine shaft – main shaft subassembly with a complex geometry was generated based on the designed data. The Finite Elements Analysis was performed using SolidWorks 3D CAD Design and COSMOSWorks software. Results predicted by the finite element method show the method presented is efficient and accurate and in good agreement with the theoretical and experimental values. Results from the current analysis can be used for further studies in designing of the turbine shaft – main shaft subassembly.

Keywords: agricultural machinery, driveline, hydrodynamic clutch, turbine shaft – main shaft assembly, finite elements analysis

1. INTRODUCTION

The requirements for the manufacturers of agricultural machinery are nowadays to make the machinery work quickly, efficiently, precisely and easily. The modern condition of design, construction and manufacture of agricultural machinery must be in accordance with the international quality and standardizations. Agricultural machinery manufacturers, in the trend towards the competitiveness and more economical agricultural production, need to cope with two different market demands for the specifications and features; one is characterized by need for high-grade products that have cost-effective performance, the other is characterized by the need for simple specification products featuring mainly low price. In such present conditions, in order to meet the demands of high-grade products featuring high performance, high durability and low price, manufacturers need to strive, not only to reduce manufacturing costs but also to reduce developing and marketing costs. Optimal design and manufacture of the agricultural machinery components, that are result of a complex chain of actions, starting with a design to match the functional demands, is important for safety and reliability [1]. CAD and finite element analysis (FEA) play a key role in the design of the agricultural machinery components. Finite element analysis allows designs to be analyzed, optimized, and revised quickly and accurately. Virtual testing and optimization is conducted early in the design cycle, thereby saving both time and money and assuring a consistent product each production run [2 - 7].

2. MODELLING OF THE TURBINE SHAFT–MAIN SHAFT SUBASSEMBLY

2.1 The 3D modelling of hydrodynamic clutch

A three-dimensional model of the hydrodynamic clutch assembly with all components, with a complex geometry, was generated based on the designed data and performed using SolidWorks 3D CAD Design. The hydrodynamic clutch in a longitudinal section is shown in Fig. 1.
3. THE FEM ANALYSIS OF THE TURBINE SHAFT-MAIN SHAFT ASSEMBLY

3.1 Meshing the turbine shaft – main shaft subassembly

Finite elements analysis was performed using COSMOSWorks software.

3.2 The calculation of stresses distribution and displacements

The obtained results are presented with a deformation scale to emphasize the distortions of turbine shaft – main shaft subassembly.

Results obtained are presented below:

4. CONCLUSIONS

The Finite Elements Analysis using COSMOSWorks software for turbine shaft – main shaft subassembly from a average power hydrodynamic clutch included in a driveline agricultural machinery was made.

Results predicted by the finite element method show the method presented is efficient and accurate and in good agreement with the theoretical and experimental values. Results from the current analysis can be used for further studies in designing of the turbine shaft – main shaft subassembly.
